

# Convolution Operation

- A **Convolution operation** is a **mathematical way to extract patterns** from data (like images).
- It works by **sliding a small matrix (called a filter or kernel)** over the image, **multiplying values**, and **summing them** to **create a new image (called a feature map or activation map)**.
- This helps the system **recognize patterns like edges, shapes, or textures**.

## What is Convolution in Simple Words?

- Convolution = **Pattern-matching process**
- We use a **filter** (also called a **kernel**) to look at **small parts of the input** (like small windows).
- The filter slides across the input and does **element-wise multiplication**, then **adds all values** to make a **single number**.
- This creates a new matrix (called a **feature map** or **convolved output**) that highlights certain features in the input.

## How It Works

### 1. Filter Slides Over Input:

- The kernel (e.g.,  $3 \times 3$  matrix) moves across the input image (left-to-right, top-to-bottom).
- At each position, it performs **element-wise multiplication** between the kernel and the overlapping region of the input, then sums the results.

### 2. Output Feature Map:

- Each computed value becomes a pixel in the output feature map, highlighting detected features (e.g., edges).

1 <small>x1</small>	1 <small>x0</small>	1 <small>x1</small>	0	0
0 <small>x0</small>	1 <small>x1</small>	1 <small>x0</small>	1	0
0 <small>x1</small>	0 <small>x0</small>	1 <small>x1</small>	1	1
0	0	1	1	0
0	1	1	0	0

Convolved  
Feature

### Example (Edge Detection):

- **Input Image (5×5) and Filter (3×3):**

Input (I):      Kernel (K):  
 [1, 1, 1, 0, 0]   [-1, -1, -1]  
 [0, 1, 1, 1, 0]   [-1, 8, -1]  
 [0, 0, 1, 1, 1]   [-1, -1, -1]  
 [0, 0, 1, 1, 0]   (Edge detector)  
 [0, 1, 1, 0, 0]

- **Convolution Output (3×3):**
  - The filter detects transitions (edges) where pixel values change sharply.

## Edge Detection

- Edge detection is → **Intensity change**

Original Image

Laplacian Edge Detection

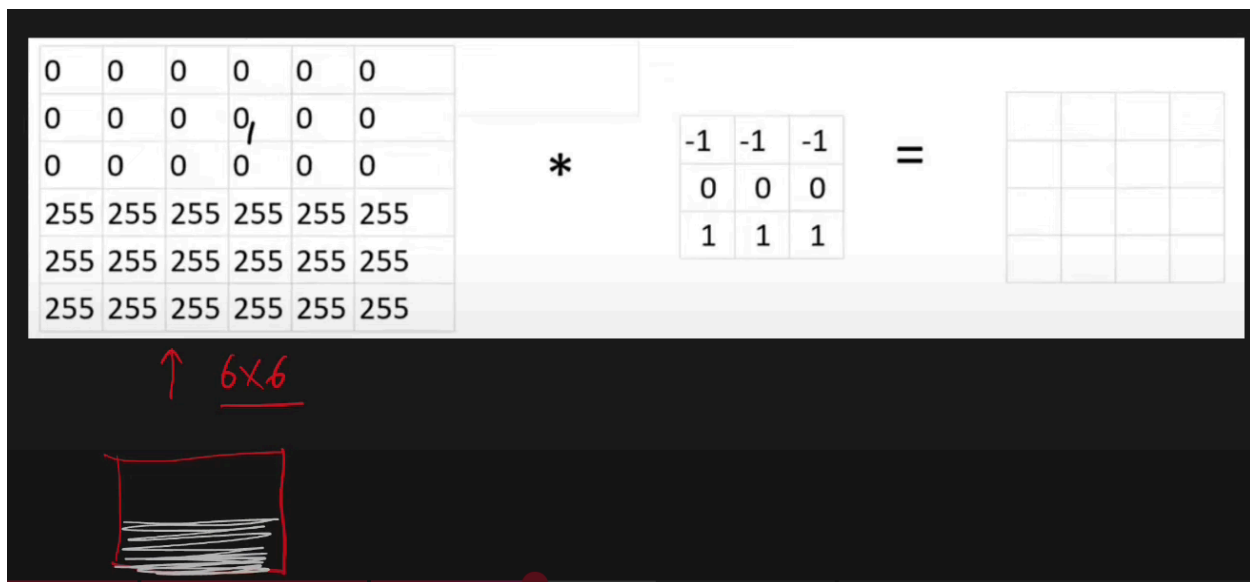

Original Image

Edge Image

How it works?

- 🙌 Above is  $6 \times 6$  image
- The above part is black and the below one is white

**Expected output:**

***We need a filter (kernel) for this (Generally a  $3 \times 3$  matrix)***

1. You put the kernel on the image
2. Multiply the respective numbers
3. Add the sum in the respective cell
4. Slide the filter

## 5. Repeat

- 🖐 Above is the filter for **horizontal** edge detector
- For **vertical** edge detection, the filter is 🖐

- Similarly, there are filters for various other edge detectors.

**We don't need to make the filters in CNN. We just give the shape of the matrix**

**CNN Demo** → <https://deeplizard.com/resource/pavq7noze2>

Image shape →  $(28 \times 28)$

Filter →  $(3 \times 3)$

Output →  **$26 \times 26$**

**Output shape =  $(n-m+1) \times (n-m+1)$**

$$\begin{array}{lcl} (28 \times 28) & \longrightarrow & (26 \times 26) \\ n \times n & & m \times m \end{array} \quad \begin{array}{lcl} (3 \times 3) & \longrightarrow & ? \\ m \times m & \longrightarrow & (n-m+1) \times (n-m+1) \end{array}$$

*(Handwritten notes:  $(26 \times 26)$  is underlined;  $(n-m+1) \times (n-m+1)$  is written below the second arrow)*

## RGB Filtering:

## Multiple Filters

- You get multiple feature maps
- The channels can act as filters for subsequent layers

## Key Parameters in Convolution

Parameter	Meaning
<b>kernel_size</b>	Size of the filter (e.g., 3x3)
<b>stride</b>	Number of steps the filter moves at a time (default: 1)
<b>padding</b>	Adds zeros around the border to preserve dimensions
<b>filters</b>	Number of different filters used (each finds a different pattern)
